(57) **ABSTRACT**

Provided is a communication control device including an
allocation unit that allocates transmit power to each of one or
more small cells so as to moderate interference on a macro
cell of a radio communication system from each small cell
that at least partially overlaps with the macro cell, a judgment
unit that, in a case in which there exists a second small cell
that exerts interference exceeding an allowed level on a first
small cell, judges whether the interference is unidirectional or
bidirectional, and a control unit that controls the interference
between the first small cell and the second small cell with a
technique that differs according to a judgment result by the
judgment unit.

COMMUNICATION CONTROL DEVICE, COMMUNICATION CONTROL METHOD, AND COMMUNICATION CONTROL PROGRAM

CROSS-REFERENCE TO RELATED APPLICATION

The present application is a national phase entry under 35 U.S.C. §371 of International Application No. PCT/JP2012/083670 filed Dec. 26, 2012, published on Aug. 29, 2013 as WO 2013/125151 A1, which claims priority from Japanese Patent Application No. JP 2012-033854 filed in the Japanese Patent Office on Feb. 20, 2012.

TECHNICAL FIELD

The present disclosure relates to a communication control device, a communication control method, and a communication control program.

BACKGROUND ART

Recently, high-speed cellular radio communication schemes such as Long Term Evolution (LTE) and WiMAX are being practically implemented, and the communication rate of radio communication services enjoyed by mobile users has greatly improved. Furthermore, if fourth-generation cellular radio communication schemes such as LTE-Advanced (LTE-A) are introduced, an even greater improvement in communication rate is anticipated.

On the other hand, the number of mobile users is increasing rapidly, and the usage of applications demanding high data rates is becoming more widespread. As a result, the development of cellular radio communication schemes is not fully satisfying all mobile users' needs. Consequently, in order to supplement macro cells and increase communication capacity, the introduction of small cells is being advanced. Small cells are a concept that encompasses femto cells, nano cells, pico cells, micro cells, and the like. Small cells are typically introduced by installing a base station (also called an access point) that is small compared to a macro cell base station (for example, an evolved Node B (eNB) in LTE). However, in areas where a macro cell and a small cell overlap, there is a risk of radio signals transmitted and received by the small cell interfering with a terminal connected to the macro cell.

In order to avoid the risk of interference due to the introduction of small cells, Patent Literature 1 below proposes a technique that cooperatively controls the transmit power and transmission rate of a macro cell and a small cell.

CITATION LIST

Patent Literature

Patent Literature 1: JP 2011-211369A

SUMMARY OF INVENTION

Technical Problem

However, when envisioning conditions in which multiple small cells are present, the technique of moderating interference by considering only the relationship between macro cell and small cell is insufficient at avoiding the risk of interference.

2

Consequently, it is desirable to provide a mechanism enabling inter-cell interference to be suitably moderated under conditions in which multiple small cells are present.

Solution to Problem

According to the present disclosure, there is provided a communication control device including an allocation unit that allocates transmit power to each of one or more small cells so as to moderate interference on a macro cell of a radio communication system from each small cell that at least partially overlaps with the macro cell, a judgment unit that, in a case in which there exists a second small cell that exerts interference exceeding an allowed level on a first small cell, judges whether the interference is unidirectional or bidirectional, and a control unit that controls the interference between the first small cell and the second small cell with a technique that differs according to a judgment result by the judgment unit.

According to the present disclosure, there is provided a communication control method including allocating transmit power to each of one or more small cells so as to moderate interference on a macro cell of a radio communication system from each small cell that at least partially overlaps with the macro cell, judging, in a case in which there exists a second small cell that exerts interference exceeding an allowed level on a first small cell, whether the interference is unidirectional or bidirectional, and controlling the interference between the first small cell and the second small cell with a technique that differs according to a result of the judging.

According to the present disclosure, there is provided a communication control system including base stations of a first small cell and a second small cell that at least partially overlap with a macro cell of a radio communication system, and a communication control device that includes an allocation unit that allocates transmit power to each of the first small cell and the second small cell so as to moderate interference from the first small cell and the second small cell on the macro cell, a judgment unit that, in a case in which one of the first small cell and the second small cell exerts interference exceeding an allowed level on the other, judges whether the interference is unidirectional or bidirectional, and a control unit that controls the interference between the first small cell and the second small cell with a technique that differs according to a judgment result by the judgment unit.

Advantageous Effects of Invention

According to technology in accordance with the present disclosure, it is possible to suitably moderate inter-cell interference under conditions in which multiple small cells are present.

BRIEF DESCRIPTION OF DRAWINGS

FIG. 1 is an explanatory diagram for describing an overview of a system.

FIG. 2A is an explanatory diagram for describing a first case of interference that may occur when multiple small cells are present.

FIG. 2B is an explanatory diagram for describing a second case of interference that may occur when multiple small cells are present.

FIG. 2C is an explanatory diagram for describing a third case of interference that may occur when multiple small cells are present.

FIG. 3 is an explanatory diagram for describing several examples of the placement of a cooperation manager for the purpose of interference control.

FIG. 4 is a block diagram illustrating an example of a configuration of a cooperation manager according to an embodiment.

FIG. 5A is a first explanatory diagram for describing the estimation of cumulative interference caused by multiple small cells.

FIG. 5B is a second explanatory diagram for describing the estimation of cumulative interference caused by multiple small cells.

FIG. 6 is a table illustrating an example of interference control schemes that may be selected according to the type of interference.

FIG. 7 is a flowchart illustrating an example of the flow of a communication control process according to an embodiment.

FIG. 8 is a flowchart illustrating an example of a detailed flow of the interference classification process illustrated in FIG. 7.

FIG. 9 is a block diagram illustrating an example of a configuration of a base station according to an embodiment.

DESCRIPTION OF EMBODIMENTS

Hereinafter, preferred embodiments of the present invention will be described in detail with reference to the appended drawings. Note that, in this specification and the drawings, elements that have substantially the same function and structure are denoted with the same reference signs, and repeated explanation is omitted.

Also, the description will proceed in the following order.

1. Overview of system
 - 1-1. Examples of small cells
 - 1-2. Types of interference
 - 1-3. Cooperation manager (CM) placement
2. Cooperation manager configuration
 - 2-1. Exemplary functional configuration
 - 2-2. Process flow
3. Small cell base station configuration
4. Conclusion

1. OVERVIEW OF SYSTEM

[1-1. Examples of Small Cells]

First, FIGS. 1 to 3 will be used to describe an overview of a system. FIG. 1 illustrates a radio communication system 1 as an example. The radio communication system 1 may be a system based on an arbitrary cellular radio communication scheme, such as LTE, W-CDMA, CDMA2000, WiMAX, or LTE-A, for example.

Referring to FIG. 1, a base station 11 (for example, an eNB in LTE) that provides a radio communication service to a terminal within a macro cell 10 is illustrated. The radius of the macro cell is typically from several hundred meters to over ten kilometers. However, in spaces such as near the boundary of the macro cell, in the shadow of a building, underground, or indoors, a problem may occur in which communication becomes unavailable or the data rate becomes insufficient, as a result of lowered strength of the radio signal from the macro cell base station. Under such conditions, small cells may be introduced in order to supplement the macro cell and increase communication capacity. As discussed earlier, small cells are a concept that encompasses femto cells, nano cells, pico cells, micro cells, and the like, and are introduced by installing

various types of small- to medium-scale base stations. Table 1 exemplifies several categories of small cell base stations.

TABLE 1

Categories and features of small cell base stations.			
Base station category	IF type	Access type	Expected location
Remote radio head (RRH)	Type 2	Open	Outdoors
Hot zone base station	Type 2	Open	Outdoors
Femto cell base station	Type 1	Closed	Indoors
Relay node	Type 1	Open	Outdoors

In Table 1, “IF type” is a classification related to the interface with a macro cell base station. An RRH and a hot zone base station with an X2 interface with a macro cell base station may be classified as Type 2, while a femto cell base station and a relay node lacking an X2 interface may be classified as Type 1. “Access type” is a classification related to how the small cell is accessed from UE. The access type of an RRH, a hot zone base station, and a relay node is open, and as a general rule, all user devices are able to connect to the small cells of these base stations. On the other hand, the access type of a femto cell base station is closed, and as a general rule, only a limited group of user devices are able to connect to a femto cell.

FIG. 1 illustrates small cell base stations 16a, 16b, 16c, and 16d. The small cell base stations 16a, 16b, 16c, and 16d respectively provide radio communication service to terminals within small cells 14a, 14b, 14c, and 14d that at least partially overlap with the macro cell 10. In FIG. 1, terminals that connect to the macro cell are indicated by black circles, whereas terminals that connect to the small cells are indicated by white circles.

In the case in which a small cell is placed within a macro cell in this way, there is a risk of radio signals transmitted and received by the small cell interfering with a terminal connected to the macrocell. In order to avoid such risk, several interference control schemes are usable. The simplest interference control scheme may be separation of the frequency bands in use. However, under conditions in which frequency resources are depleted, it is not necessarily possible to always assign to the small cell a frequency band that differs from the frequency band in use by the macro cell. Consequently, an interference control scheme that cooperatively controls the transmit power or transmission rate of the macro cell and the small cell is beneficial, such as that proposed by the above Patent Literature 1. However, in the case in which multiple small cells are present, an interference control scheme that considers only the relationship between macro cell and small cell is insufficient.

[1-2. Types of Interference]

FIGS. 2A to 2C illustrate three typical cases of interference that may occur in the case in which multiple small cells are present. In the first case illustrated in FIG. 2A (interference case A), bidirectional interference occurs between two mutually neighboring small cells 14a and 14b. More specifically, in the area where the small cells 14a and 14b overlap, a terminal 18a connected to the small cell 14a receives interference caused by radio signals transmitted and received within the small cell 14b. Similarly, a terminal 18b connected to the small cell 14b receives interference caused by radio signals transmitted and received within the small cell 14a.

In the second case illustrated in FIG. 2B (interference case B), unidirectional interference from a small cell 14c to a small cell 14b occurs. More specifically, radio signals transmitted and received within the small cell 14b do not reach any of the

5

terminals **18c** connected to the small cell **14c**. Radio signals transmitted from the base station **16c** of the small cell **14c** may exert interference exceeding an allowed level on a terminal **18b** connected to the small cell **14b**. This may occur because excessively large transmit power is allocated to the base station **16c** as a result of the presence of an obstacle between the base station **11** of the macro cell and the base station **16c** of the small cell **14c**.

In the third case illustrated in FIG. 2C (interference case C), cumulative interference from two small cells **14a** and **14d** negatively influences a terminal connected to the macro cell. More specifically, for a terminal **12a** positioned at a place between the small cells **14a** and **14d**, the sum of the interference caused by radio signals from a terminal **18a** connected to the small cell **14a** and the interference caused by radio signals from a terminal **18d** connected to the small cell **14d** exceeds an allowed level.

In order to suitably moderate the interference that is characteristic to these conditions in which multiple small cells are present, in the technology according to the present disclosure, a functional entity called a cooperation manager (CM) is introduced.

[1-3. Cooperation Manager (CM) Placement]

The cooperation manager may be placed on any communication node able to communication with the base station of a small cell. FIG. 3 is an explanatory diagram for describing several examples of the placement of a cooperation manager. In FIG. 3, an LTE-based network architecture is illustrated as an example. In an LTE-based network architecture, the base station (eNB) **11** of a macro cell **10** is connected to a core network **20**. The core network **20** is implemented as the Evolved Packet Core (EPC), including a P-GW, an S-GW, and an MME, for example. The core network **20** is additionally connected to an external network **30**. The external network **30** is an Internet Protocol (IP) network, also called a packet data network (PDN), and various application (AP) servers may be implemented on the external network **30**.

Each of the nodes illustrated in FIG. 3 respectively has a role like the following. Note that although only representative nodes are illustrated herein, other types of nodes may also be included the network architecture.

Home Subscriber Server (HSS): a server that manages subscriber identification information, profile information, authentication information, and the like.

Mobility Management Entity (MME): an entity that exchanges non-access stratum (NAS) signals with UE, and conducts mobility management, session management, paging, and the like. The MME is connected to multiple eNBs.

PDN-Gateway (P-GW): a gateway, positioned at the junction between the EPC and the PDN, that assigns IP addresses to UE, attaches and deletes IP headers, and the like. The P-GW may also manage billing.

Serving-Gateway (S-GW): a gateway, positioned at the junction between the E-UTRAN and the EPC, that routes packets in the user plane. The S-GW becomes an anchor point in the case of UE handover between eNBs or between UTRANs.

Evolved Node B (eNB): a base station that realizes the radio link within a macro cell. Conducts radio resource management (RRM), radio bearer control, scheduling, and the like.

In a network architecture like that exemplified in FIG. 3, a cooperation manager may be placed as a new control node within the core network **20** (CM1). Alternatively, a cooperation manager may be placed as a new function on an existing control node (the MME, for example) within the core network

6

20 (CM2). Alternatively, a cooperation manager may be placed as a new function on the base station (eNB) of a macro cell (CM3). Alternatively, a cooperation manager may be placed as a new function on the base station of a small cell (CM4). Alternatively, a cooperation manager may be placed as a new server device within the external network **30** (CM5).

In any placement, the cooperation manager communicates with the base station of a macro cell and the base stations of small cells on a signaling link that includes the X2 interface (or some other logical/physical interface), the core network **20** or the external network **30**, or the like. Additionally, the cooperation manager first allocates resources and transmit power to the small cells while accounting for the relationships between the macro cell and the individual small cells, and then categorizes the interference cases to address, and also controls the interference that is characteristic to the conditions in which multiple small cells are present.

2. COOPERATION MANAGER CONFIGURATION

[2-1. Exemplary Functional Configuration]

FIG. 4 is a block diagram illustrating an example of a configuration of a cooperation manager **100**. Referring to FIG. 4, the cooperation manager **100** is equipped with a communication unit **110**, a storage unit **120**, and a control unit **130**.

(1) Communication Unit

The communication unit **110** is a communication module by which the cooperation manager **100** communicates with other nodes. The communication unit **110** may include a wireless communication module that includes an antenna and a radio frequency (RF) circuit, or include a wired communication module such as a local area network (LAN) port.

(2) Storage Unit

The storage unit **120** uses a storage medium such as a hard disk or semiconductor memory to store programs and data for the operation of the cooperation manager **100**. For example, the storage unit **120** may store allocations of resources and transmit power to each small cell made by an allocation unit **132** discussed later. Also, the storage unit **120** may store a judgment threshold used when a judgment unit **134** discussed later categorizes an interference case.

(3) Control Unit

The control unit **130** corresponds to a processor such as a central processing unit (CPU) or a digital signal processor (DSP). The control unit **130** causes various functions of the cooperation manager **100** to operate by executing a program stored in the storage unit **120** or another storage medium. In the present embodiment, the control unit **130** includes three function modules: an allocation unit **132**, a judgment unit **134**, and an interference control unit **136**.

(3-1) Allocation Unit

The allocation unit **132** allocates transmit power to each of one or more small cells so as to moderate the interference from each small cell on the macro cell of the radio communication system.

More specifically, in the present embodiment, the allocation unit **132** first computes per resource block allowed transmit power for each small cell. The allowed transmit power may take a larger value with greater path loss from the base station of a small cell to the base station of the macro cell. The allowed transmit power of a small cell may be moderated for resource blocks that are prioritized for usage in the macro cell. The allocation unit **132** may also compute per resource block the allowed transmit power of a small cell according to the technique described in the above Patent Literature 1, for

example. Note that in the case in which the allowed transmit power computed for a small cell exceeds power corresponding to the number of terminals supportable by that small cell, the allocation unit 132 may decrease the allowed transmit power of that small cell.

Next, the allocation unit 132 allocates resources and transmit power to the broadcast channel of each small cell on the basis of the computed allowed transmit power. The broadcast channel herein may include a synchronization channel for terminal cell search and synchronization, as well as a control channel for signaling system information. For example, the allocation unit 132 may place the broadcast channel of a small cell in a resource block where relatively large transmit power is allowed for that small cell. In the case where a consecutive F (frequency direction)×T (time direction) number of resource blocks is required for a broadcast channel, the broadcast channel may be placed in a set of consecutive F×T resource blocks in which the minimum value of the allowed transmit power does not fall below a designated power level.

In the case in which there is contention among small cells for the resources to be allocated to the broadcast channel, the allocation unit 132 may adjust the allocation of resources and transmit power according to the access type of the small cell.

For example, the allocation unit 132 may prioritize the communication opportunities of open-access type small cells over closed-access type small cells. In other words, in the case of resource contention between a closed-access type small cell and an open-access type small cell, the allocation unit 132 first places the broadcast channel of the open-access type small cell in a resource block with larger allowed transmit power. Subsequently, the allocation unit 132 decreases the allowed transmit power of the closed-access type small cell. As a result, the resource contention may be resolved. Alternatively, the allocation unit 132 may also place the broadcast channel of the closed-access type small cell in the (set of) resource blocks with the next largest allowed transmit power, without decreasing the allowed transmit power of the closed-access type small cell. By prioritizing open-access type small cells in this way, it becomes possible to provide communication opportunities to more users. Also, the installation of open-access type small cells is encouraged, and the system's overall ability to support terminals may be raised.

Also, in the case of resource contention between multiple open-access type small cells, the allocation unit 132 may adjust the allocation of resources and transmit power according to the estimated numbers of terminals in those small cells. An estimated number of terminals may be determined on the basis of terminal position data reported from a terminal or a base station to the cooperation manager. For example, the allocation unit 132 decreases the allowed transmit power of a small cell with a lower estimated number of terminals. As a result, the resource contention may be resolved. Alternatively, the allocation unit 132 may also place the broadcast channel of a small cell with a lower estimated number of terminals in the (set of) resource blocks with the next largest allowed transmit power, without decreasing the allowed transmit power of the small cell.

Also, in the case of resource contention between multiple closed-access type small cells, the allocation unit 132 may adjust the allocation of resources and transmit power so that communication opportunities are fairly distributed among those small cells. In this case, the allocation unit 132 uniformly decreases the allowed transmit power of the small cells contending for resources (for example, with a fixed decrement or a fixed rate of decrease). As a result, the resource contention may be resolved. Alternatively, the allocation unit 132 may also place the broadcast channel of any of

the small cells in the (set of) resource blocks with the next largest allowed transmit power, without decreasing the allowed transmit power of the small cell.

(3-2) Judgment Unit

After the allocation unit 132 decides the placement and transmit power for the broadcast channel of each small cell, it becomes possible to estimate the placement and transmit power for the data channels of each small cell. The uplink and downlink data channels may be placed in resource blocks between periodically placed broadcast channels, for example. The transmit power of a data channel may be estimated to be equal to the transmit power of the broadcast channel, or estimated to be lower.

The judgment unit 134, on the basis of the resource and transmit power allocation by the allocation unit 132, estimates the interference caused by the transmission of radio signals on the broadcast channel and data channels from each small cell. Subsequently, in the case of interference that exceeds an allowed level, the judgment unit 134 executes a classification of interference cases.

More specifically, for respective pairs of small cells, the judgment unit 134 estimates per resource block the interference level from the second small cell at the cell edge of the first small cell. Subsequently, in the case in which the estimated interference level exceeds an allowed level in a number of resource blocks that exceeds a designated ratio, the judgment unit 134 may judge that the interference on the first small cell from the second small cell is not allowed. In this case, the judgment unit 134 additionally judges whether the interference between the first and second small cells is unidirectional or bidirectional. At this point, in the case of bidirectional interference, the judgment unit 134 classifies the interference between the first and second small cells into the interference case A that was described using FIG. 2A. On the other hand, in the case of unidirectional interference, the judgment unit 134 classifies the interference between the first and second small cells into the interference case B that was described using FIG. 2B. Note that the above designated ratio may be statically configured (such as 10% to 20%, for example), or dynamically configured according to a parameter such as the transmission duty cycle per small cell.

Also, in the present embodiment, the judgment unit 134 may additionally judge whether or not the cumulative interference from multiple small cell onto a terminal connected to the macro cell exceeds an allowed level. For example, the judgment unit 134 estimates the interference level caused by radio signals from each of the multiple small cells at a place between the base stations of the multiple small cells, and compares the cumulative value of the estimated interference level to an allowed level. In the example of FIG. 5A, the normal line dropped from the eNB 11 to the line joining the base station 16a of the small cell 14a and the base station 16d of the small cell 14d is extended to the edge of the macro cell 10. The cumulative interference may also be evaluated by supposing that a terminal connected to the macro cell is present on a reference line RL along such a normal line. Such an evaluation is valuable in the case in which interference caused by downlink signals of the small cells is dominant. On the other hand, in the example of FIG. 5B, boundaries 15a and 15d of the areas in which a designated signal level (−110 dBm/6 MHz, for example) is detected are computed for the small cells 14a and 14d, respectively. The cumulative interference may also be evaluated by supposing that a terminal connected to the macro cell is present in the overlapping portion of these areas (the shaded portion in the drawing). Such an evaluation is valuable in the case in which the cause of the dominant interference is not specified. The judgment

unit **134** follows such a procedure to detect a pair of small cells that exerts cumulative interference exceeding an allowed level on a macro cell terminal, and classifies the cumulative interference into the interference case C that was described using FIG. 2C.

(3-3) Interference Control Unit

The interference control unit **136** controls inter-cell interference in conditions in which multiple small cells are present, according to a technique that differs depending on the judgment result by the judgment unit **134**. FIG. 6 illustrates an example of interference control schemes that may be selected by the interference control unit **136** according to a judgment result (that is, an interference classification) by the judgment unit **134**.

For example, the interference control unit **136** controls the scheduling of at least one of the first and second small cells so that the same radio resource (that is, a resource block) is not simultaneously used by a pair of small cells involved in the interference case A. Resource blocks in which interference is likely to occur may also be alternately allocated to the first and second small cells in a round-robin scheme. Also, more or earlier resource blocks may be allocated to one of the small cells according to a priority that may depend on parameters such as latency, throughput, or other communication requirements, application importance, or communication quality.

Also, the interference control unit **136** issues a request for decreasing transmit power to the base station of the small cell on the interfering side of a pair of small cells involved in the interference case B, for example. The interference case B may be resolved if the base station of the small cell on the interfering side accepts the decrease in transmit power. In the case in which the base station of the small cell on the interfering side does not accept the decrease in transmit power, the interference control unit **136** may control the scheduling of at least one of small cells on the interfered side and the interfering side so that the same radio resource is not simultaneously used.

Also, in the case in which cumulative interference classified into the interference case C is estimated, the interference control unit **136** requests the base station of the macro cell to increase the interference immunity of radio signals transmitted between the macro cell terminal receiving the cumulative interference and the base station of the macro cell, for example. The interference immunity of a radio signal may be increased by increasing the transmit power, or by using a lower-rate modulation scheme, for example. Alternatively, the interference control unit **136** may control the scheduling of the small cell on the interfering side so that radio resources used in the macro cell are not simultaneously used in the small cell on the interfering side. In addition, the interference control unit **136** may also request the base station of the small cell on the interfering side to decrease the transmit power.

Note that although FIG. 6 illustrates three exemplary interference cases, any of these interference cases may be omitted from classification, or additional interference cases may be adopted. Also, interference control may be executed in units of multiple resource blocks instead of being executed in units of single resource blocks. As a result, the load on the cooperation manager **100** and the signaling load on the network may be alleviated.

[2-2. Process Flow]

(1) Overall Flow

FIG. 7 is a flowchart illustrating an example of the flow of a communication control process by a cooperation manager **100** according to the present embodiment.

Referring to FIG. 7, first, the allocation unit **132** computes per resource block allowed transmit power for each small cell

(step **S110**). Next, the allocation unit **132** allocates resources and transmit power for a broadcast channel to each small cell, on the basis of the computed allowed transmit power (step **S120**).

Next, the judgment unit **134**, on the basis of the resource and transmit power allocation by the allocation unit **132**, estimates the interference caused by the transmission of uplink signals and downlink signals on the data channels from each small cell (step **S130**). Next, the judgment unit **134** executes the interference classification process to be described using FIG. 8 (step **S140**).

Subsequently, the interference control unit **136** moderates interference between cells under conditions in which multiple small cells are present, according to a technique (for example, one of the techniques illustrated in FIG. 6) that differs depending on the result of the interference classification process (step **S150**).

(2) Interference Classification Process

FIG. 8 is a flowchart illustrating an example of a detailed flow of the interference classification process in step **S140** of FIG. 7.

Referring to FIG. 8, first, the judgment unit **134** selects one from among one or more pairs of small cells operating within the macro cell being controlled as the current pair (step **S141**).

Next, the judgment unit **134** judges whether or not the estimated interference level from at least one of the small cells in the current pair on the other small cell exceeds an allowed level in a number of resource blocks exceeding a designated ratio (step **S142**). At this point, the process proceeds to step **S146** in the case in which neither small cell satisfies the above condition as the interfering side. On the other hand, the process proceeds to step **S143** in the case in which the above condition is satisfied.

In step **S143**, the judgment unit **134** judges whether or not the interference discussed above is bidirectional (step **S143**). For example, the interference is bidirectional in the case in which both small cells satisfy the condition described in step **S142** as the interfering side. If the interference is bidirectional, the judgment unit **134** classifies the interference involving the current pair into the interference case A (step **S144**). On the other hand, if the interference is unidirectional, the judgment unit **134** classifies the interference involving the current pair into the interference case B (step **S145**).

Meanwhile, in step **S146**, the judgment unit **134** judges whether or not the cumulative interference estimated at a place between the small cells of the current pair exceeds an allowed level of the macro cell (step **S146**). At this point, if the estimated cumulative interference exceeds the allowed level of the macro cell, the judgment unit **134** classifies the interference involving the current pair into the interference case C (step **S147**). Otherwise, the level of interference involving the current pair is sufficiently low, and thus the interference is not classified into any of the interference cases.

After that, if a next small cell pair with an unfinished classification exists, the process returns to step **S141**. On the other hand, if classification has finished for all pairs, the interference classification process of FIG. 8 ends (step **S148**).

3. SMALL CELL BASE STATION CONFIGURATION

The small cell base station **200** constitutes a communication control system together with the cooperation manager **100** discussed above. FIG. 9 is a block diagram illustrating an example of a configuration of a small cell base station **200** according to the present embodiment. Referring to FIG. 9, the

11

base station **200** is equipped with a radio communication unit **210**, a network communication unit **220**, a storage unit **230**, and a control unit **240**.

(1) Radio Communication Unit

The radio communication unit **210** is a radio communication module for providing a radio communication service to a terminal connected to the small cell. The radio communication unit **210** includes an antenna and an RF circuit. The transmit power of a radio signal transmitted from the radio communication unit **210** is moderated to be within a range controlled by the cooperation manager **100**.

(2) Network Communication Unit

The network communication unit **220** is a communication module for communication between the small cell base station **200** and a control node such as the cooperation manager **100**. The network communication unit **220** may include a wireless communication module that may be shared with the radio communication unit **210**, or include a wired communication module such as a LAN port.

(3) Storage Unit

The storage unit **230** uses a storage medium such as a hard disk or semiconductor memory to store programs and data for the operation of the base station **200**. For example, the storage unit **230** may store allocations of resources and transmit power designated by the cooperation manager **100**.

(4) Control Unit

The control unit **240** corresponds to a processor such as a CPU or DSP. The control unit **240** causes various functions of the base station **200** to operate by executing a program stored in the storage unit **230** or another storage medium. In the present embodiment, the control unit **240** includes two function modules: a configuration unit **242** and a communication control unit **244**.

(4-1) Configuration Unit

The configuration unit **242** configures communication parameters for radio communication with a terminal connected to the small cell, in accordance with an interference control signal received by the network communication unit **220**. For example, the configuration unit **242** configures a broadcast channel in a resource block specified by the interference control signal. Also, the configuration unit **242** configures the transmit power of the radio communication unit **210** to a value specified by the interference control signal. In the case of receiving a request to decrease the transmit power from the cooperation manager **100**, the configuration unit **242** decreases the transmit power configured in the radio communication unit **210**. Note that the configuration unit **242** may also not accept the above request in the case of judging that a desired communication quality cannot be maintained if the transmit power is decreased.

(4-2) Communication Control Unit

The communication control unit **244** controls radio communication with a terminal connected to the small cell. For example, the communication control unit **244** broadcasts a synchronization signal for cell search and synchronization as well as system information on a broadcast channel configured by the configuration unit **242**. Also, the communication control unit **244** allocates to each terminal resource blocks on data channels that may be positioned between broadcast channels. Subsequently, the communication control unit **244** causes the radio communication unit **210** to receive uplink signals and transmit downlink signals in accordance with the resource block allocation. Additionally, the communication control unit **244** controls the transmit power of each terminal connected to the small cell, to be within a range allowed by the cooperation manager **100**.

12

4. CONCLUSION

The foregoing thus describes an embodiment of technology according to the present disclosure in detail using FIGS. 1 to 9. According to the embodiment discussed in the foregoing, interference between small cells is at least classified according to whether the interference is unidirectional or bidirectional, and interference is moderated with a technique that differs depending on the classification. Consequently, compared to an interference control scheme that does not depend on interference classification, it is possible to more suitably moderate inter-cell interference under conditions in which multiple small cells are present.

For example, in the case of unidirectional interference, the base station of the small cell on the interfering side may be requested to decrease the transmit power. Consequently, by decreasing the transmit power of the small cell that is obtained too many communication opportunities, it is possible to moderate interference while maintaining the communication opportunities of the small cell on the interfered side.

As another example, in the case of bidirectional interference, the scheduling of two small cells involved with the interference may be controlled so that these small cells do not use the same radio resource simultaneously. Consequently, interference may be moderated by fairly reducing communication opportunities for small cells that are equally responsible for interference.

As another example, in the case in which the cumulative interference from multiple small cells exerts interference exceeding an allowed level on a macro cell terminal, the cumulative interference is also moderated. Consequently, it is possible to safely introduce multiple small cells while suitably protecting communication by macro cell terminals. For example, by increasing the interference immunity of a radio signal on the macro cell side, the relative level of cumulative interference with respect to the allowed interference level may be moderated. In this case, it is possible to prevent the adverse effects of interference without reducing the communication opportunities of the small cells involved with the cumulative interference.

According to the embodiment discussed in the foregoing, resources and transmit power are first allocated to a broadcast channel of a small cell, and then the interference caused by transmission on a data channel from the small cell is estimated in units of single or multiple resource blocks on the basis of the allocation. Consequently, compared to a technique that does not distinguish types of channels when estimating interference, it is possible to rationally estimate the interference level that may vary per resource block.

Note that the series of control processes conducted by the devices described in this specification may be realized in any of software, hardware, and a combination of software and hardware. A program constituting software is stored in advance in a storage medium (a non-transitory medium) provided internally or externally to each device, for example. Each program is then loaded into RAM at runtime and executed by a processor such as a CPU, for example.

The foregoing thus describes preferred embodiments of the present disclosure in detail and with reference to the attached drawings. However, the technical scope of the present disclosure is not limited to such examples. It is clear to persons ordinarily skilled in the technical field of the present disclosure that various modifications or alterations may occur insofar as they are within the scope of the technical ideas stated in the claims, and it is to be understood that such modifications or alterations obviously belong to the technical scope of the present disclosure.

Additionally, the present technology may also be configured as below.

(1)

A communication control device including:

an allocation unit that allocates transmit power to each of one or more small cells so as to moderate interference on a macro cell of a radio communication system from each small cell that at least partially overlaps with the macro cell;

a judgment unit that, in a case in which there exists a second small cell that exerts interference exceeding an allowed level on a first small cell, judges whether the interference is unidirectional or bidirectional; and

a control unit that controls the interference between the first small cell and the second small cell with a technique that differs according to a judgment result by the judgment unit.

(2)

The communication control device according to (1), wherein

in a case in which the interference between the first small cell and the second small cell is unidirectional, the control unit requests a base station of the second small cell to decrease transmit power.

(3)

The communication control device according to (1) or (2), wherein

in a case in which the interference between the first small cell and the second small cell is bidirectional, the control unit controls scheduling of at least one of the first small cell and the second small cell so that the same radio resource is not used simultaneously in the first small cell and the second small cell.

(4)

The communication control device according to (2), wherein

in a case in which the base station of the second small cell does not accept the request, the control unit controls scheduling of at least one of the first small cell and the second small cell so that the same radio resource is not used simultaneously in the first small cell and the second small cell.

(5)

The communication control device according to any one of (1) to (4), wherein

the judgment unit additionally judges whether or not cumulative interference from a plurality of small cells on a terminal connected to the macro cell exceeds an allowed level, and

in a case in which the cumulative interference is judged to exceed the allowed level, the control unit controls at least one base station of the macro cell or base station of the plurality of small cells so that the cumulative interference is moderated.

(6)

The communication control device according to (5), wherein

the judgment unit estimates an interference level caused by a radio signal from each of the plurality of small cells at a place between the base stations of the plurality of small cells, and compares a cumulative value of the estimated interference level to the allowed level.

(7)

The communication control device according to (5) or (6), wherein

in a case in which the cumulative interference is judged to exceed the allowed level, the control unit increases an interference immunity of a radio signal transmitted between the terminal and base station of the macro cell.

(8)

The communication control device according to (5) or (6), wherein

in a case in which the cumulative interference is judged to exceed the allowed level, the control unit controls scheduling of the plurality of small cells so that a radio resource used by the terminal in the macro cell is not used simultaneously in the plurality of small cells.

(9)

The communication control device according to any one of (1) to (8), wherein

the allocation unit allocates a resource and transmit power to a broadcast channel of each small cell on the basis of allowed transmit power for each small cell computed per resource block, and

the judgment unit estimates interference caused by transmission of a radio signal from each small cell on the basis of the allocation of the resource and the transmit power to each small cell.

(10)

The communication control device according to (9), wherein

the allocation unit allocates the resource and the transmit power so that a communication opportunity of an open-access type small cell is prioritized over a closed-access type small cell.

(11)

A communication control method including:

allocating transmit power to each of one or more small cells so as to moderate interference on a macro cell of a radio communication system from each small cell that at least partially overlaps with the macro cell;

judging, in a case in which there exists a second small cell that exerts interference exceeding an allowed level on a first small cell, whether the interference is unidirectional or bidirectional; and

controlling the interference between the first small cell and the second small cell with a technique that differs according to a result of the judging.

(12)

A communication control system including:

base stations of a first small cell and a second small cell that at least partially overlap with a macro cell of a radio communication system; and

a communication control device that includes

an allocation unit that allocates transmit power to each of the first small cell and the second small cell so as to moderate interference from the first small cell and the second small cell on the macro cell,

a judgment unit that, in a case in which one of the first small cell and the second small cell exerts interference exceeding an allowed level on the other, judges whether the interference is unidirectional or bidirectional, and

a control unit that controls the interference between the first small cell and the second small cell with a technique that differs according to a judgment result by the judgment unit.

15

The invention claimed is:

1. A communication control device comprising:

an allocation unit that allocates transmit power to each of one or more small cells so as to moderate interference on a macro cell of a radio communication system from each small cell that at least partially overlaps with the macro cell;

a judgment unit that, in a case in which there exists a second small cell that exerts interference exceeding an allowed level on a first small cell, judges whether the interference is unidirectional or bidirectional; and

a control unit that controls the interference between the first small cell and the second small cell with a technique that differs according to a judgment result by the judgment unit.

2. The communication control device according to claim 1, wherein

in a case in which the interference between the first small cell and the second small cell is unidirectional, the control unit requests a base station of the second small cell to decrease transmit power.

3. The communication control device according to claim 1, wherein

in a case in which the interference between the first small cell and the second small cell is bidirectional, the control unit controls scheduling of at least one of the first small cell and the second small cell so that the same radio resource is not used simultaneously in the first small cell and the second small cell.

4. The communication control device according to claim 2, wherein

in a case in which the base station of the second small cell does not accept the request, the control unit controls scheduling of at least one of the first small cell and the second small cell so that the same radio resource is not used simultaneously in the first small cell and the second small cell.

5. The communication control device according to claim 1, wherein

the judgment unit additionally judges whether or not cumulative interference from a plurality of small cells on a terminal connected to the macro cell exceeds an allowed level, and

in a case in which the cumulative interference is judged to exceed the allowed level, the control unit controls at least one base station of the macro cell or base station of the plurality of small cells so that the cumulative interference is moderated.

6. The communication control device according to claim 5, wherein

the judgment unit estimates an interference level caused by a radio signal from each of the plurality of small cells at a place between the base stations of the plurality of small cells, and compares a cumulative value of the estimated interference level to the allowed level.

7. The communication control device according to claim 5, wherein

16

in a case in which the cumulative interference is judged to exceed the allowed level, the control unit increases an interference immunity of a radio signal transmitted between the terminal and base station of the macro cell.

8. The communication control device according to claim 5, wherein

in a case in which the cumulative interference is judged to exceed the allowed level, the control unit controls scheduling of the plurality of small cells so that a radio resource used by the terminal in the macro cell is not used simultaneously in the plurality of small cells.

9. The communication control device according to claim 1, wherein

the allocation unit allocates a resource and transmit power to a broadcast channel of each small cell on the basis of allowed transmit power for each small cell computed per resource block, and

the judgment unit estimates interference caused by transmission of a radio signal from each small cell on the basis of the allocation of the resource and the transmit power to each small cell.

10. The communication control device according to claim 9, wherein

the allocation unit allocates the resource and the transmit power so that a communication opportunity of an open-access type small cell is prioritized over a closed-access type small cell.

11. A communication control method comprising:

allocating transmit power to each of one or more small cells so as to moderate interference on a macro cell of a radio communication system from each small cell that at least partially overlaps with the macro cell;

judging, in a case in which there exists a second small cell that exerts interference exceeding an allowed level on a first small cell, whether the interference is unidirectional or bidirectional; and

controlling the interference between the first small cell and the second small cell with a technique that differs according to a result of the judging.

12. A communication control system comprising:

base stations of a first small cell and a second small cell that at least partially overlap with a macro cell of a radio communication system; and

a communication control device that includes

an allocation unit that allocates transmit power to each of the first small cell and the second small cell so as to moderate interference from the first small cell and the second small cell on the macro cell,

a judgment unit that, in a case in which one of the first small cell and the second small cell exerts interference exceeding an allowed level on the other, judges whether the interference is unidirectional or bidirectional, and

a control unit that controls the interference between the first small cell and the second small cell with a technique that differs according to a judgment result by the judgment unit.
